Total energy expenditure and water turnover during suppression

BRENT C. RUSTY, TOM C. SHRYVER, TERENCE S. SODIA, TYRIS
Human Performance Laboratory, The University of Montana, Missoula, MT

During a 24-hr period, energy expenditure (EE) was measured by indirect calorimetry (IC) and water turnover (WT) was measured by deuterium dilution. The purpose of this study was to determine the relationship between EE and WT during suppression. Ten subjects were studied during a 24-hr period of suppression. EE was measured by IC and WT was measured by deuterium dilution. The results showed that EE and WT were both suppressed during suppression. The relationship between EE and WT was not significant.

Previous research has shown that the daily energy expenditure (DEE) of humans is related to body mass and activity level. However, the relationship between DEE and water turnover (WT) has not been well established. The purpose of this study was to determine the relationship between DEE and WT during suppression. Ten subjects were studied during a 24-hr period of suppression. DEE was measured by indirect calorimetry (IC) and WT was measured by deuterium dilution. The results showed that DEE and WT were both suppressed during suppression. The relationship between DEE and WT was not significant.

Supplemental Feeding of Self-Selected Work and Wildfire Suppression

BRENT C. RUSTY, DALE A. SCHNEIDER, BRIE
Human Performance Laboratory, The University of Montana, Missoula, MT

The purpose of this study was to determine the effect of supplemental feeding on energy expenditure (EE) and water turnover (WT) during suppression. Ten subjects were studied during a 24-hr period of suppression. EE was measured by indirect calorimetry (IC) and WT was measured by deuterium dilution. The results showed that EE and WT were both suppressed during suppression. The relationship between EE and WT was not significant.

The purpose of this study was to determine the effect of supplemental feeding on energy expenditure (EE) and water turnover (WT) during suppression. Ten subjects were studied during a 24-hr period of suppression. EE was measured by indirect calorimetry (IC) and WT was measured by deuterium dilution. The results showed that EE and WT were both suppressed during suppression. The relationship between EE and WT was not significant.

Exogenous Carbohydrate Spares Muscle Glycogen in Men and Women during 10 h of Exercise

STEPHANIE G. BARRIS, ANDREW E. MCLAUGHLIN, STEVEN J. GARNER, and BRENT C. RUSTY
Human Performance Laboratory, The University of Montana, Missoula, MT

The purpose of this study was to determine the effect of exogenous carbohydrate on muscle glycogen stores during 10 h of exercise. Ten subjects were studied during a 10-h period of exercise. Muscle glycogen stores were measured by biopsy. The results showed that exogenous carbohydrate spared muscle glycogen stores during exercise.

The purpose of this study was to determine the effect of exogenous carbohydrate on muscle glycogen stores during 10 h of exercise. Ten subjects were studied during a 10-h period of exercise. Muscle glycogen stores were measured by biopsy. The results showed that exogenous carbohydrate spared muscle glycogen stores during exercise.

- Energy Demands (DLW w/WLFF, WS100, Ironman, Iditarod, AFSOC)
- Hydration Demands (D2O w/WLFF, WS100, Ironman, Iditarod, AFSOC, Badwater)
- Reasons for Fatigue/Counter measures (Natick, WLFF)
- Instrumentation (physiological monitor systems lab and field)
- Mobility in the Field (data collection in varied environments)
- Environmental stress (heat, cold, hypoxia, recovery, gene response)
- Innovation/Creative application in a mission **oriented variable environment** to improve translation to the end user!

Muscle glycogen utilization during prolonged exercise on successive days

DAVID L. COSTILL, RICHARD BOWERS, GEORGE BRANAM, AND KENNETH SPARKS
Human Performance Laboratory, Ball State University, Muncie, Indiana 47306

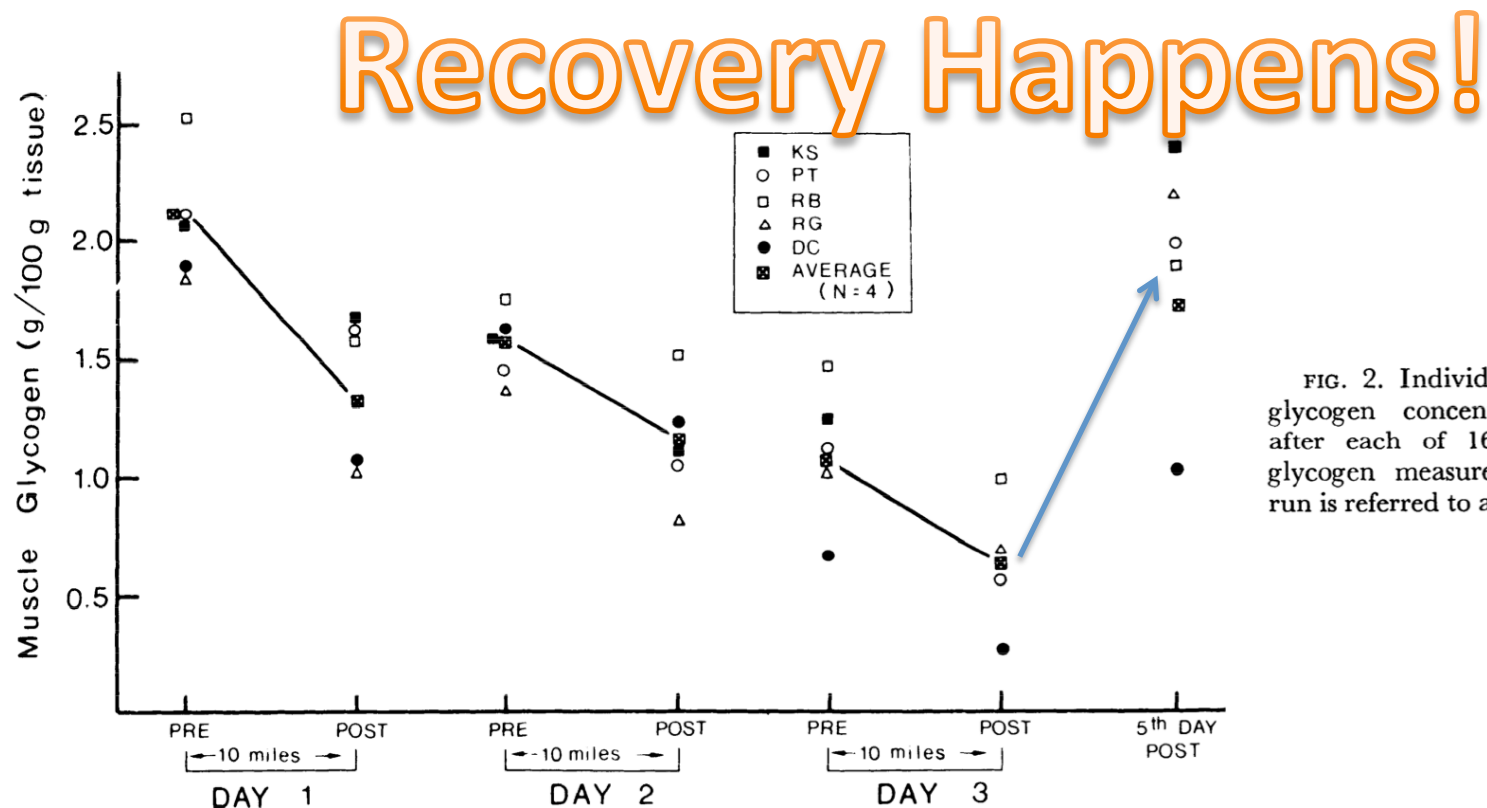

FIG. 2. Individual and mean muscle glycogen concentrations before and after each of 16.1-km runs. Muscle glycogen measured 5 days after 3rd run is referred to as "5th day post."

April 15 , 1971

Muscle glycogen utilization during prolonged exercise on successive days

DAVID L. COSTILL, RICHARD BOWERS, GEORGE BRANAM, AND KENNETH SPARKS
Human Performance Laboratory, Ball State University, Muncie, Indiana 47306

The fact that the diets of our subjects contained only moderate amounts (40–50 %) of carbohydrate may explain why muscle glycogen replacement was incomplete for *subjects DC, RB, and PT* even after 5 days of rest. These observations hold unmistakable implications for men who must exercise exhaustively on successive days.

Recovery becomes...trendy?!

Received 3 May 2002; accepted in final form 2 July 2002

Fig. 1. Patterns of muscle glycogen storage during recovery as determined by nuclear magnetic resonance spectroscopy for the carbohydrate-protein (CHO-Pro; ■), isocarbohydrate (LCHO; △), and isocaloric carbohydrate (HCHO; ●) supplements. Supplements were provided immediately after and 2 h after exercise. *CHO-Pro significantly different from LCHO and HCHO ($P < 0.05$). †CHO-Pro significantly different from LCHO ($P < 0.05$). ‡HCHO significantly different from LCHO ($P < 0.05$).

Fig. 2. Total muscle glycogen storage in the vastus lateralis during 4 h of recovery from intense cycling. Treatments were with CHO-Pro, LCHO, and HCHO supplements provided immediately after and 2 h after exercise. *Significantly different from HCHO and LCHO ($P < 0.05$).

High rates of muscle glycogen resynthesis after exhaustive exercise when carbohydrate is coingested with caffeine

David J. Pedersen, Sarah J. Lessard, Vernon G. Coffey, Emmanuel G. Churchley, Andrew M. Wootton, They Ng, Matthew J. Watt, and John A. Hawley

School of Medical Sciences, RMIT University, Bundoora, Victoria, Australia

Submitted 18 October 2007; accepted in final form 30 April 2008

Fig. 1. Skeletal muscle glycogen content immediately after exercise (0 h) and after 1 h and 4 h of recovery following cycling to volitional fatigue [$\sim 70\%$ peak $\dot{V}O_{2\text{peak}}$]. During recovery subjects consumed 1 g carbohydrate/kg body mass (BM) (CHO) or 1 g carbohydrate/kg BM + 8 mg caffeine/kg BM (Caff). *Significant difference vs. 0 h; #significant difference vs. 1 h; †significant difference, CHO vs. Caff 4 h ($P < 0.05$). All values are

8 mg/kg BW

75 kg rider...600 mg!

400mg of Caffeine

Consider the near 6 hour half life
and how this may compromise
sleep quality!

The addition of fenugreek extract (*Trigonella foenum-graecum*) to glucose feeding increases muscle glycogen resynthesis after exercise

B. C. Ruby, S. E. Gaskill, D. Slivka, and S. G. Harger

Fig. 3. Changes in muscle glycogen (vastus lateralis) in response to the oral glucose and experimental feedings (GLU vs. GLU + 4-OH-Ile). Feedings occurred immediately after post exercise biopsy (0 post exercise) and again at 120 minutes (4 hr post feed). * – significant increase from 0 post exercise (GLU), $p < 0.05$, ** – significant increase from 0 post exercise (GLU + 4-OH-Ile), $p < 0.05$, † – 4 hr post feed (GLU + 4-OH-Ile) vs. 4 hr post feed (GLU), $p < 0.05$
